## Introduction

Altering fluxes for overcoming metabolic bottlenecks have traditionally been approached by genetic engineering of a single or few metabolic genes. This strategy struggles to overcome the subjacent regulation thus the outcome has frequently shown to be of limited success. Transcription factors have the potential of controlling several fluxes in an organism, hence manipulating expression of these proteins can provide an alternative tool for overcoming metabolic bottlenecks. This approach has previously been demonstrated in yeast with great success for production of ethanol (Schuurmans et al., 2008).

In the present study the effect of modulation of TFs in *A. niger*, which is an industrially important micro-organism. The strategy described in this work focuses on regulation connected to pH. It was chosen as an important process parameter, due to its significant influences on both organic acid and enzyme production.

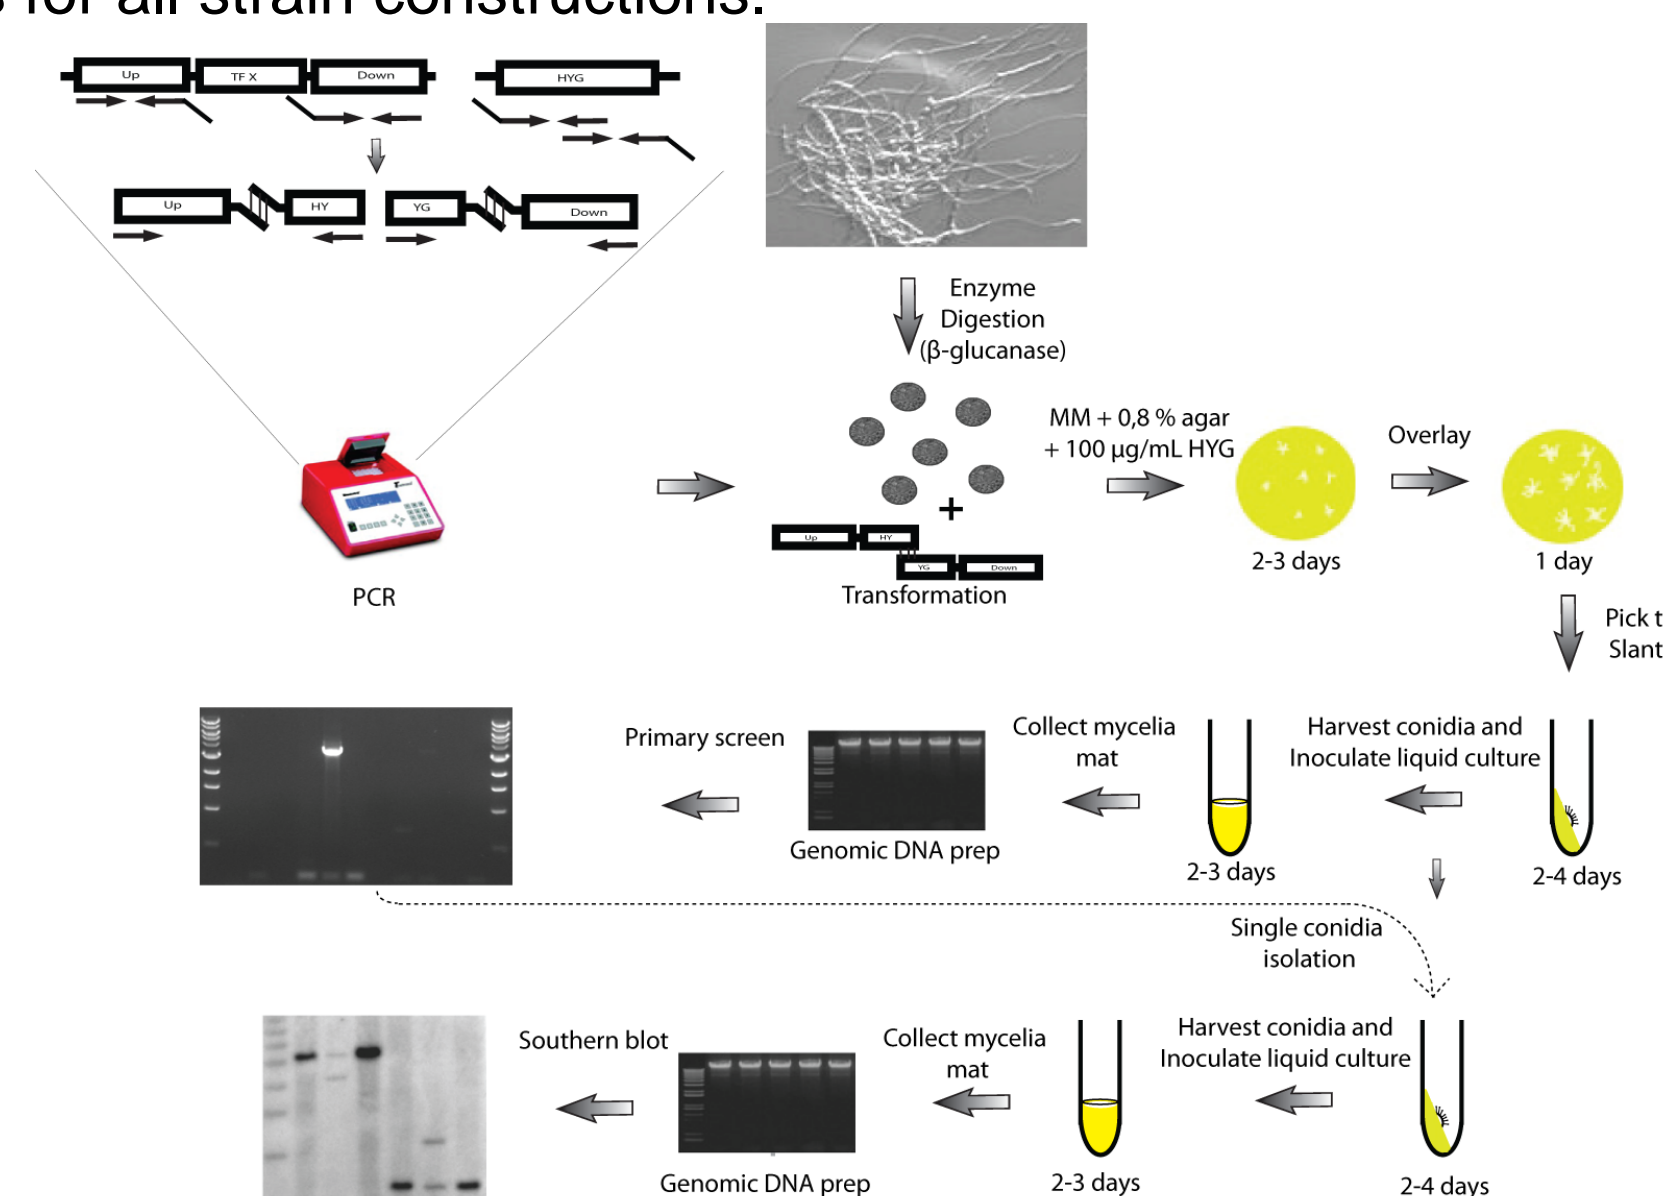

## Locating targets

In order to locate targets for knockout, data from a previous transcription analysis (Andersen et al., 2009) was utilized. Several putative TF with pH responding behavior was identified and formed the basis for gene-knockout.

## Strain construction

The *A. niger* ATCC 1015 was used as Wild-type strain and was the basis for all strain constructions.

## Physiological characterisation

### Screening

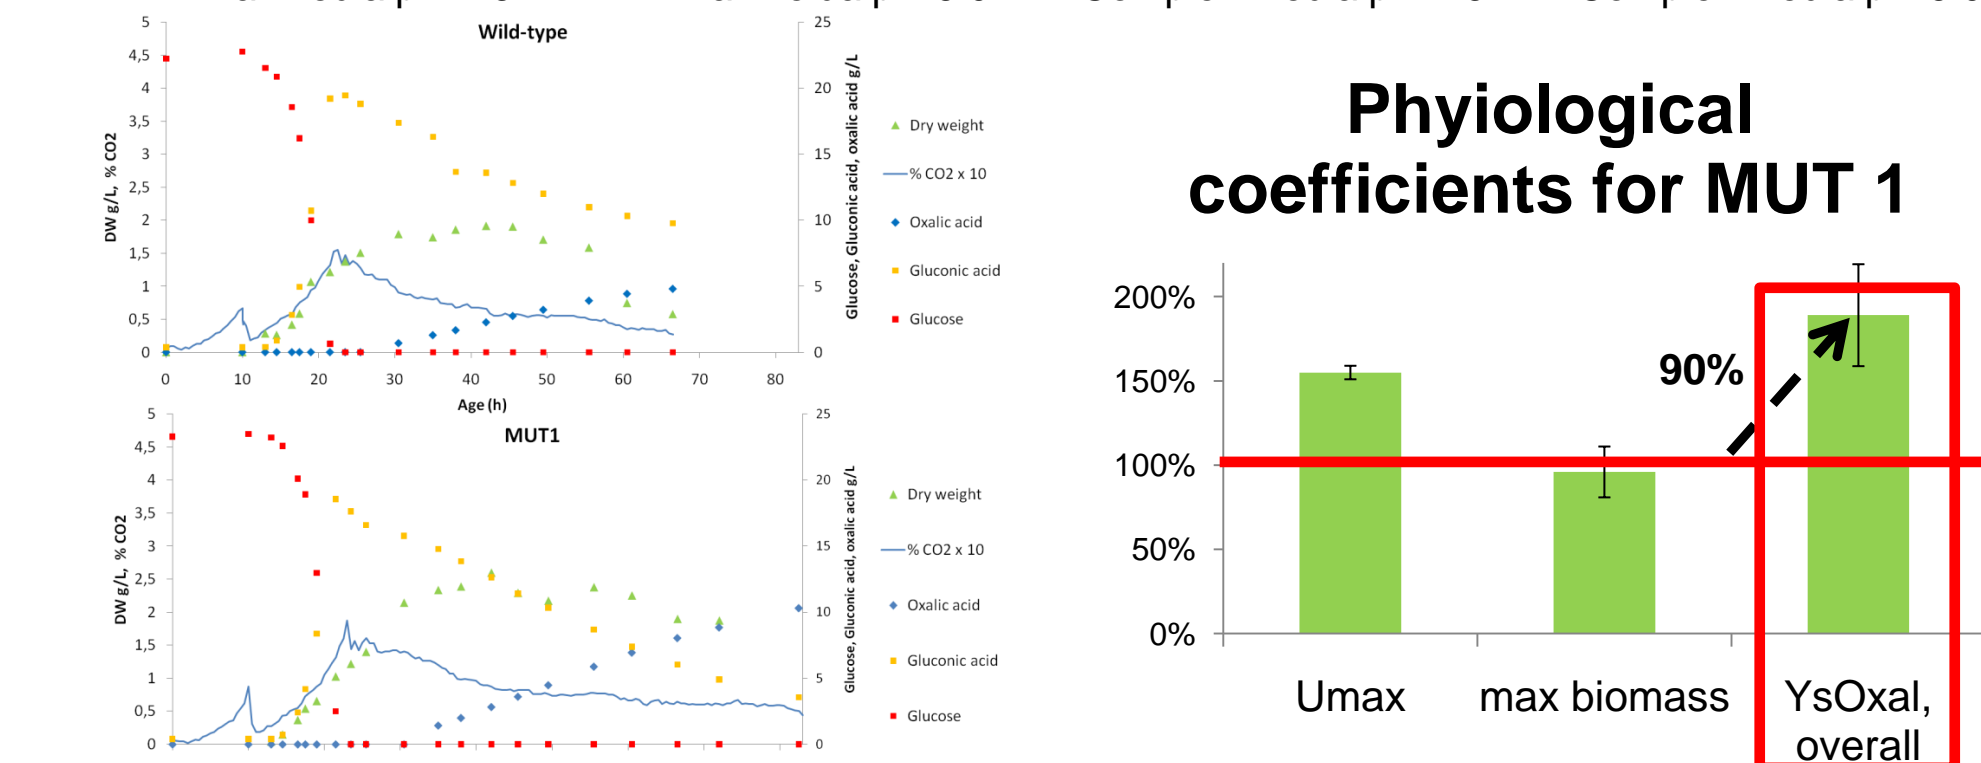

Three novel TF mutants were screened for protease activity and acid production and compared against Wild-type and a previously described protease deficient mutant  $\Delta$ prtT (P. J Punt et al., 2008). The experiments were performed for 4 days as 6 mL stationary cultures in minimal- and complex medium.

### Batch fermentations

To further characterize MUT 1, which expressed an oxalic acid overproducing phenotype (OOP), this mutant was cultivated in 2L scale bioreactors.

Parameters	Germination	Fermentation
Aeration	0.10 vvm	1 vvm
Stir speed	200 RPM	1000 RPM
pH	3.0	6.0

## Conclusion

- Several pH responding TF deficient mutants were constructed and screened for protease activity and acid production
- One mutant had an oxalic acid overproducing phenotype (OOP) and one mutant had indications of being protease deficient.
- The OOP mutant was further characterized in 2L scale bioreactors, and a 90 % ( $\pm 25\%$ ) increase of oxalic acid on glucose was seen.
